Soap: the science behind it and tools and tips for selecting a hand soap that’s right for your facility.

Megan J. DiGiorgio MSN, RN, CIC, FAPIC
Introduction

Hand hygiene is the primary measure to prevent transmission of pathogens in healthcare facilities and alcohol-based hand rub (ABHR) is designated as the preferred method for performing hand hygiene by the 2002 Centers for Disease Control and Prevention (CDC) and the 2009 World Health Organization (WHO) hand hygiene guidelines. However, soap and water also plays a critical role in hand hygiene, namely when hands are visibly soiled or contaminated with blood or other bodily fluids and when there are outbreaks of *Clostridium difficile* or norovirus.

Background

Prior to publication of the 2002 CDC hand hygiene guidelines, soap was the predominant hand hygiene product. Today, ABHR represents about two-thirds of all hand hygiene product sales in healthcare. While ABHR is the primary pillar of hand hygiene due to its many proven advantages such as superior efficacy, speed of procedure, better compliance, and skin health benefits, soap remains an important aspect of the hand hygiene regimen that is not always given as much consideration as it deserves.

The Science of Soap

Soap’s Mechanism of Action

When selecting the type of soap for a healthcare facility, it’s important to first understand how soap works. The general mechanism of action is lifting and suspending oil, dirt, and other organic substances from hands so they can be rinsed down the drain, much like cleaning a dirty dish. Alkali metal salts of fatty acids, such as sodium laurate and potassium cocoate, are traditionally used as soaps. Soaps are classified as surfactants (surface active agents) as they possess both polar (ionic/hydrophilic) and non-polar (long hydrocarbon/hydrophobic) groups. When soap is added to water, tiny clusters called micelles are formed due to aggregation of hydrophobic segments. The ionic segments of surfactants orient outward of the core aggregates/micelles. Hydrophobic segments of micelles have strong affinity towards oil-type dirt and germs, and the hydrophilic segments of micelles attract toward the water-soluble materials. As a result, soaps are capable of cleaning skin and other substrates by removing both water soluble and water-insoluble dirt from the substrates and suspending them in aqueous solutions.

In recent decades, detergents have also been used as soaps. Detergents have similar functional groups as soaps but their hydrophilic groups can be of various types including anionic, non-ionic, cationic, or amphoteric, instead of carboxylic salts. Examples of detergents include sodium laureth sulfates, alkyl polyglycosides, cocamidopropylbetaine and fatty alkyl amine oxides.
With plain or non-antimicrobial soaps, organic substances and some microorganisms on the skin are removed, but the commensal resident organisms that are reduced quickly regrow to a normal level. The target organisms for removal are transient, non-resident organisms that may cause illness. Antimicrobial soaps also contain an antibacterial active ingredient that interacts with and kills bacterial cells. Some actives (e.g. chlorhexidine gluconate or CHG) may deposit on the skin’s surface in low levels, which keeps the number of microorganisms to a reduced level by static activity for an extended period of time. There are several active ingredients that are used in antimicrobial soap formulations in healthcare, and their spectrum of activity and efficacy against microorganisms varies and can be greatly affected by the other non-active ingredients in the formula (Table 1).

Lack of Consensus around Antimicrobial versus Non-antimicrobial Soap
Both CDC and WHO hand hygiene guidelines allow the use of either an antimicrobial or a non-antimicrobial soap, and due to a lack of evidence demonstrating clinical benefit (i.e. resulting reduction of infection rates), do not recommend one over the other. Clinical data are lacking due to complexity of designing such a study, difficulty eliminating confounding variables, cost, and reasons of practicality. However, studies of germ reduction on the hands support that ABHR is most efficacious, followed by antimicrobial soap, followed by non-antimicrobial soap as least efficacious (Table 2). That said, healthcare facilities are permitted the choice between antimicrobial and non-antimicrobial soap, or may use a combination of the two.

A good way to approach the decision of whether to choose an antimicrobial or a non-antimicrobial soap is to consider risk reduction. Table 3 shows comparisons of the average log_{10} reductions against bacteria after a single hand wash using water, non-antimicrobial soap, and antimicrobial soap. The greatest risk reduction will be achieved by using an antimicrobial soap. For example, if a healthcare

**Handwashing Technique**

While there’s a lack of consensus on type of soap, there’s more consensus around handwashing technique. The CDC recommends wetting hands first with water, applying a manufacturer-recommended volume of product to hands, and rubbing vigorously for at least 15 seconds, covering all surfaces of the hands and fingers, followed by rinsing and drying thoroughly with a disposable towel. The WHO recommends a similar method, although they provide more specifics when it comes to vigorously rubbing all surfaces of hands and fingers, separating the process into very specific steps such as palm to palm, fingers interlaced, rotational rubbing of thumb and so forth. Despite published recommendations, HCW have been observed not rubbing for an adequate amount of time. In ten observational studies, the duration of handwashing ranged on average from as little as 6.6 seconds to as much as 30 seconds.5

Soap is still a critical component of a hand hygiene program and should be used when hands are visibly soiled or contaminated with blood or other bodily fluids, before eating, and after using the restroom.

HCW skin health is an important factor affecting hand hygiene compliance and there is a perception that ABHR cause skin damage. But, if ABHRs are properly formulated, soap and water use is generally the main factor affecting skin condition with current hand hygiene products today.
There is a science to properly formulating soap, and poorly formulated soaps will be very harsh on the skin. As they lift the dirt, they will also remove natural components of the skin (corneocytes and lipids) that help keep skin healthy. This sets up a vicious dry skin cycle that worsens with each soap wash.

Traditionally, antimicrobial soaps have been less mild to skin than non-antimicrobial soaps; however, the latest generation of antimicrobial soaps can provide antimicrobial efficacy as well as improved skin mildness.

Choosing a well-formulated soap with low potential for irritation can help mitigate skin health issues and will be discussed later in this paper. But first, it’s important to understand the regulatory pathways for soap.

The Regulatory Landscape
The Food and Drug Administration (FDA) Division of Over-The-Counter (OTC) Drug Products regulates the use of topical antiseptic drug products used in healthcare. Antimicrobial soaps used in healthcare settings fall under this category. There are two regulatory pathways for these products; one is the New Drug Application (NDA) and the other is the Monograph process.

The Healthcare Monograph
The Healthcare OTC Monograph Final Rule represents the regulatory standards for the marketing of antimicrobial soaps not covered by a New Drug Application. The Monograph establishes conditions under which certain OTC active ingredients are generally recognized as safe and effective. The Monograph is a “recipe book” that specifies allowed ingredients, doses, product form, indications for use, warnings and also provides a set of labeling and testing requirements for manufacturers.

Finally, any insult to the SC barrier then leads to an increase in epidermal nerve density that can cause sensations of stinging, burning, itching, tingling and tightness. This is often recognized during contact with ABHR, but it is the soap, specifically surfactants, that created the condition. In addition, environmental stressors such as low relative humidity, using hot water, and low quality of paper towels can also affect the skin. Therefore, it is critical to provide the right product formulation to minimize damage and keep the “bricks and mortar” intact. These tightly packed “bricks” help restore the skin’s natural protection against the environment, chemicals, and pathogens.

As discussed earlier, antimicrobial soaps remove dirt, oil, and organic substances from the skin; however, they also have the addition of an active ingredient to help kill germs.
Alternative Regulatory Pathway – New Drug Application

Products that contain active ingredients not included in the Monograph or combinations of active ingredients follow a different regulatory pathway. The New Drug Application (NDA) pathway is the vehicle through which drug sponsors (the person or entity who assumes responsibility for the marketing of a new drug) formally propose that the FDA approve a new pharmaceutical for sale and marketing in the U.S. The FDA reviews the application to determine whether the drug is safe and effective when used as proposed, whether the drug’s labeling is appropriate, and whether the drug was manufactured in a way that maintains the quality of the drug. If the NDA is approved, then the drug may be marketed and sold in the U.S. This is how prescription drugs are brought to market. As an example, chlorhexidine gluconate (CHG) is an active ingredient used in a variety of applications in healthcare today, including hand washes, patient bathing, pre-operative skin preparation, impregnated dressings and a variety of other antiseptic uses to prevent colonization and infection by bacteria. CHG is not an active ingredient covered by the Monograph and therefore requires a NDA.

Choosing a Soap for Your Healthcare Facility

With all of the considerations around soap, selecting the right product can be confusing. Additionally, there can be reluctance to changing hand hygiene products in healthcare facilities due to the many considerations that go along with it, such as potential for a period of adjustment among HCW, the logistics involved with switching dispensers, and disruptions to the clinical workflow. When considering a product change or if you’re currently using a soap active ingredient with an uncertain future, it’s important to carefully select the right product and right dispensing solution for your facility.

As previously discussed, soap has not been given as much consideration as ABHR when healthcare facilities have chosen hand hygiene products.

Poorly formulated soap can have profound negative effects on HCW skin condition and can contribute to a cycle of skin damage that is reinforced by avoidance of ABHR and continued over-use of soap. Therefore, selecting well-formulated products is an important foundational aspect of a hand hygiene and an infection prevention and control program.

How to Select the Right Soap for Your Facility

Factors to consider when selecting soap for your healthcare facility are summarized in Table 4. Deciding whether to use an antimicrobial or a non-antimicrobial soap is often the first decision. Many healthcare facilities take a risk-reduction approach by utilizing an antimicrobial soap for added protection, while some choose a hybrid approach and deploy antimicrobial soap to high acuity areas such as intensive care units, hematology-oncology areas, and surgical areas. Others use non-antimicrobial soaps throughout the facility. While the evidence around whether antimicrobial soaps result in better clinical outcomes remains elusive, it is estimated that as much as two-thirds of the soaps sold into healthcare today is antimicrobial.

Key Factors to Consider When Selecting a Soap

Developing a truly mild, yet effective soap that can be used multiple times during a HCW’s shift is a significant technical challenge, so it’s important to carefully assess products under consideration. It can be very helpful to evaluate soaps within the context of three important factors: efficacy, skin health, and aesthetics (skin feel). It is important to note that more sensitive skin often undergoes a period of adjustment during which the skin’s natural defenses must adapt to any product change that is made. As a result, trialing products for a minimum of two-to-three weeks is essential since the stratum corneum renewal time or “turnover” typically occurs in that timeframe. If there are skin adjustment issues that occur during the beginning of a trial period, they should also subside within that two-to-three week window. It is also advisable that if trialing more than one product back-to-back, a washout period of around one week between
products is scheduled during which time the previous product is re-implemented. The WHO provides two protocols for evaluation of tolerability and acceptability of ABHR which can be adapted for soap evaluations.\textsuperscript{10}

**Efficacy.** For antimicrobial soaps, it is not only important to consider different active ingredients, but also evaluate the efficacy of finished formulations. The Healthcare Personnel Handwash Test is the only FDA-accepted test for healthcare hand wash products and it measures the reduction of a transient market organism (\textit{Serratia marcescens}) on the hands of adult subjects after a single product use and after 10 consecutive product uses. The FDA requires antimicrobial hand wash and hand rub agents achieve a $2\log_{10}$ reduction at Application 1 and a $3\log_{10}$ reduction at Application 10.\textsuperscript{11} Product manufacturers should supply customers with this data for products being sold into healthcare.

**Skin health.** How a product affects the skin health of end-users is especially important in environments such as healthcare where repeated use scenarios are common. While the OTC Monograph does not specify irritancy testing requirements, ensuring skin tolerance of products is critical to maximizing HCW acceptance and hand hygiene compliance.\textsuperscript{1} Industry standard is a 14-day human cumulative irritancy assay with delayed challenge. This type of study is designed to assess the irritation potential of test product and involves daily, consecutive application of product in “patches” to the forearm of human subjects for 14 days. A control material or product is also included in the study. Dermal reactions, including erythema, edema, and other features indicative of irritation, are scored by expert visual assessments using a standard scale. A mean cumulative irritation score on a scale of 0-4 is reported with lower numbers indicating lower potential for skin irritation and allergic contact dermatitis. Forearm controlled application tests are also used to determine irritation or skin improvement effects of products under more “real world” conditions over an extended period of time. The most important tests, however, are field or clinical tests that determine irritation or skin improvement effects of products with realistic conditions and behaviors in clinical settings.

**Aesthetics/Skin Feel.** Product aesthetics and skin feel are focused towards end-user acceptance. Aesthetic considerations can begin with how the product looks (color), the product form (foam or liquid), and the sensory experience during use which it lathers and rinses. The bottom line is that if HCW do not like a product, they are less likely to use it,\textsuperscript{12} so aesthetic and skin feel considerations should not be minimized.

Balancing efficacy, skin health, and skin feel can be difficult to accomplish, but with proper formulation, of both ABHRs and soaps, it is possible to achieve this balance.
Table 5. Factors to Consider when Selecting a Soap for a Healthcare Facility

<table>
<thead>
<tr>
<th>Factor</th>
<th>Considerations</th>
</tr>
</thead>
</table>
| **Antimicrobial vs. Non-Antimicrobial Soap** | • Determine level of “risk tolerance”  
  o For greatest risk reduction, choose an antimicrobial soap  
  • Consider a single soap product approach or a hybrid approach (e.g. antimicrobial in high acuity areas only)  
  o A hybrid approach can add complexity for Environmental Services (EVS) |
| **Efficacy (Antimicrobial Soaps)** | • Product should meet FDA efficacy requirements defined in OTC Monograph  
  o Solicit product manufacturer for technical bulletin |
| **Skin Health/Mildness** | • Maintains skin condition with repeated use  
  • Solicit skin health testing data from product manufacturer  
  o **14 day irritancy test** is used to determine exaggerated irritant potential that may be cumulative with repeated exposure of a material.  
  o **Forearm controlled application test** is used to determine irritation or skin improvement effects of products under more “real world” conditions over an extended period time. As part of this test, skin hydration, TEWL, skin erythema, redness and dryness and other measures may be conducted to evaluate product performance.  
  • Field or home-use tests are used to determine irritation or skin improvement effects of products with realistic conditions & behaviors |
| **Aesthetics (Skin Feel)** | • Color  
  o Color can be used to connote or visually depict features and benefits of the product (ex. aloe-containing products are often green and perceived as soothing)  
  o Some facilities prefer dye-free products whenever possible  
  • Format (foam vs. liquid) - this is purely a preference  
  • Lather - product should have an acceptable lather  
  • Rinse - product should rinse easily and leave behind a “clean feeling”  
  • Scent/odor/fragrance  
  o Fragrance can be a positive aspect of the sensory experience, and in one study had a positive effect on hand hygiene compliance.\(^{13}\)  
  o Some facilities have a fragrance-free policy.  
  o Fragrance is often used to minimize the base odor of raw ingredients and active ingredients which can often have an unpleasant odor.  
  o Fragrance can either be synthetic or natural (e.g. essential oils).  
  o If carefully selected, fragrance can be used in levels appropriate for the healthcare environment. |
Conclusion
When faced with the challenge of choosing a new soap, it is important for key decision makers to be armed with as much knowledge around soap as possible. Although ABHR should remain the primary method for performing hand hygiene, soap continues to be an important piece of the hand hygiene regimen. Careful consideration should be given when selecting soap due to its potential for adverse skin effects if not properly formulated. Evaluating soap and ABHR in terms of efficacy, skin health, aesthetics/skin feel, and regulatory stability can be helpful. As always, allowing HCWs the opportunity to trial products and provide input is a critical aspect of product acceptance. While selecting the right soap may not be easy, being well-informed about the options and key selection factors can help make the process easier.
